

Midterm Project

Cloud-based PE Malware Detection API

Deadline: Sunday 4/12/2020 11:59pm

The purpose of this term project is to demonstrate your practical skills in implementing and deploying machine learning models for malware classification. The technical implementation of this project is comprised of three main tasks that need to be completed sequentially:

Task 1 - Training: In this task, you will be creating and training a deep neural network based on the MalConv architecture to classify PE files as malware or benign. As for the dataset, you will be using the EMBER-2017 v2 (<https://github.com/endgameinc/ember>). Besides the references provided in this repository, the following two talks at BSides San Francisco 2018 and the CAMLIS 2019 conferences present detailed overviews of this dataset, as well as hints on how to use EMBER to train malware classifiers:

- https://youtu.be/TzW_R36iv48
- <https://www.youtube.com/watch?v=MsZmnUO5IkY>

If you explore the EMBER repository, you will find that it comes with a sample implementation of MalConv (<https://github.com/endgameinc/ember/tree/master/malconv>). This sample is a wonderful resource to base your implementation on. However, note that this code is 2 years (i.e., a lifetime in ML) old, and does not precisely conform to the requirements of this project.

- **Implementation:** The model must be implemented in Python 3.x using TensorFlow (1.x or 2.x) and Keras, and needs to be coded and documented in a Jupyter Notebook. You can work in native Python for coding and testing the model if you wish, but afterwards you will need to convert your Python code into a Jupyter notebook. Similar to the notebooks we've seen in the exercises, you must also add textual description blocks to the notebook to document and explain the different parts of your code.
- **Training:** This model may take a long time to train on your personal computers (from 7-8 hours to a couple of days, depending on the config), unless you already have a powerful NVIDIA GPU (1080 TI or better). Alternatively, you can use the following cloud platforms to speed up the training:
 - **Google Colab** – You are already familiar with Colab, but here are a couple of tutorial if you need to refresh your memory:
 - <https://youtu.be/inN8seMm7UI>
 - <https://youtu.be/vVe648dJOdl>

- **Amazon AWS Sagemaker:** Since you all have \$50 worth of AWS credits through your Amazon Educate account, you can also use the Sagemaker to train your models on AWS. We have not talked about Sagemaker in the class before, and if you wish to go with option, you will need to spend some time on learning the basics of Sagemaker –which will be worth the time, having Sagemaker on your resume makes it far more attractive to employers. Here are some tutorials on how to use Sagemaker to build and train Keras models:
 - <https://blog.betomorrow.com/keras-in-the-cloud-with-amazon-sagemaker-67cf11fb536>
 - <https://github.com/aws-samples/amazon-sagemaker-keras-text-classification>
 - <https://www.youtube.com/watch?v=8Vj7OaR4DcA>
 - https://www.youtube.com/watch?v=2_z2kgkt5AM

IMPORTANT:

Make sure that you monitor the spending of your charges on AWS. You only have \$50 of credits and you will need to keep some of it for the next tasks. Ideally, you should limit the cost of training to \$10. See the following tutorial to learn how to define budgets on AWS:
<https://aws.amazon.com/getting-started/tutorials/control-your-costs-free-tier-budgets/>

- **Post-Training:** Once your model is trained, save and store the model. Then, create a function (or method) that takes a PE file as its argument, runs it through the trained model, and returns the output (i.e., Malware or Benign).

Task 2 - Deploy your model on the cloud: In this task, you will be using Amazon Sagemaker to deploy your model on the cloud, and create an endpoint (~ API) so that other applications can make use of the model. While this might sound very complicated, you will find that it is actually quite simple to deploy models using Sagemaker. To learn about the procedure, you can follow this tutorial:

- Video: <https://youtu.be/8ygCyvRZ074>
- Jupyter Notebook:
https://github.com/jeffheaton/t81_558_deep_learning/blob/master/t81_558_class_13_02_clo ud.ipynb

Task 3 – Create a client: This task is quite simple as well: create a Python code that loads a PE file, converts it into a feature vector that is compatible with your MalConv/EMBER model, runs the vector on the cloud API, and then prints the results (i.e., Malware or Benign – or probabilities of each). You can find a sample implementation here: <https://github.com/endgameinc/ember/tree/master/malconv>

Deliverables:

- **Presentation and demo video:** A short (<15m) video, in which you describe the technical details of your project, and demonstrate your implementation of all three tasks. You can assume that your audience are peers who want to learn how to replicate your work.
 - To record the video, you can use any screen recording software. Examples include Zoom and Camtasia.
 - The video must be uploaded on Youtube. However, if you wish to keep the video private (i.e., not visible to anyone outside of the class), you can post it as an “unlisted” video (see: https://support.google.com/youtube/answer/157177?hl=en&ref_topic=9257428).
- **Report:** A report, between 4 to 10 pages, comprised of:
 - An overview of the project and requirements
 - Details of your technical approach for each task
 - Performance analysis (e.g., accuracy, precision, recall, F-1, confusion matrix, average latency of malware detection with the API, etc.)
 - References (bibliography)
- **Github Repository:** Create a dedicated Github repository for this project, push the corresponding files (incl. the notebooks, code files, and report) to this repository, and create a README.MD file to introduce the project, describe the file structure, and provide links to your report and video demo.
 - You can make this repository private if you wish, but note that the entire point of these deliverables is to help with building your online portfolio.

Submission: Please submit a clone of your repository as a .zip file. Also, include a link to your repository in submission description. Note that the repository must contain the report, as well as a link to the presentation.
